SIG-Service Catalog Introduction

Doug Davis - dug@us.ibm.com - @duginabox

Applications are rarely islands

- Often applications leverage ancillary "Services"
 - E.g. Application stores data in database

- Critical to application's success
 - But developers shouldn't spend their time managing them

Services - an overloaded term

- Kubernetes "Services"
 - Applications running in the cluster accessible via DNS discovery
- Platform managed/hosted Services
 - o e.g. Object Storage
- External Services 3rd Party Services
 - o e.g. Twillio

Access to services can be challenging

- Creating and managing services is non-trivial
 - Duplication of effort across teams
 - Ops team manages it for you on their schedule
 - Managing credentials could be problematic
 - Sent via email, sticky-notes, etc...
 - Where are they stored? Plain text in config files?
 - Each service has its own set of provisioning APIs
- Let's shift the burden to the Platform via self-service model
 - "Tell us what you need and we'll manage it for you"
 - Service Credentials are protected and provided at runtime

What if ...?

```
$ svcat marketplace
   CLASS
                  PLANS
                                     DESCRIPTION
+----+
 mysql
         free
                                Simple SQL
           basic
           enterprise
          free
 mongodb
                                No-SQL DB
$ svcat provision myDB --class mysql --plan free
$ svcat bind myDB
```

Credentials (and connection info) in "myDB" secret

The magic

Cluster Admin:

- Service Brokers are registered with Kubernetes
 - Each Broker manages one or more Services
 - Each Service offers a set of variant-QoSs/Plans
- Services are available via a "Marketplace" in Kubernetes

\$ svcat marketplace

Developer:

- Chooses a Service from the Marketplace
- Kubernetes talks to owning Broker to provision it and obtain the credentials
- Secret (credentials, connection info) is available to the app

\$ svcat provision myDB...

\$ svcat bind myDB

Making it all possible

- API between Kubernetes (or CF) and a Service Broker
 - get list of services / provision / deprovision / bind / unbind
- Abstracts the Service Lifecycle APIs
- Service Brokers
 - Manage all aspects of Service's lifecycle
 - User Initiated: Create, Delete, Provide Credentials
 - Automatic: Auto-Scale, Backup, Recovery, QoS, ...
 - Hosted anywhere in or out of the Platform
 - Application is usually unaware

Why?

Application Developers

- Can focus on their business logic
- Services managed by the experts
- Self-service model speeds up CI/CD timelines
- Platforms can do more for you e.g. sharing of services across clusters & platforms

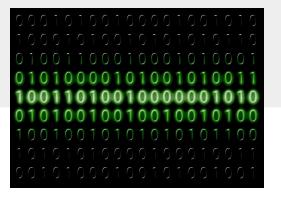

Service Providers

- Low barrier or entry for new Service Providers
- Interop: easily integrated into environments that supports the API
 - Kube, CloudFoundry, custom platforms (e.g. IBM Cloud, SAP)
- With ease of access to services, an increase in their usage (\$)

Demo

YAML all the things

```
apiVersion: servicecatalog.k8s.io/v1beta1
kind: ServiceInstance
metadata:
 name: myDB
spec:
  serviceClassName: mysql
  planName: free
apiVersion: servicecatalog.k8s.io/v1beta1
kind: ServiceBinding
metadata:
 name: myDB
spec:
  instanceRef:
    name: myDB
```

Credentials and connection info in "myDB" secret

Service Catalog Summary

Why?

- Help developers discover and connect to 3rd party services
- Allowing them to focus on their business logic
 - Ask for the service connection information provided at runtime

Status

- Kubernetes incubator project
- Can be deployed into any Kubernetes cluster via a Helm chart
- Beta

One last thing about Services

A service can be just about anything

- Data & Analytics e.g. DBs, ElasticSearch
- Integration e.g. Box, Twitter, SendGrid
- Utilities e.g conversions, speech to text
- Infrastructure networks, volumes, routing
- DevOps monitoring, metrics, auto-scaling
